

# VPS/ – THE TOWER

DOC NO. RL-Z0-VPS-A   REV. A   RIPOSTE LABORATORIES

Runs on the cheap server. One stream in, every viewer out.

| FILE                            | GOES WHERE                        | PURPOSE                                                                                                                |
|---------------------------------|-----------------------------------|------------------------------------------------------------------------------------------------------------------------|
| <code>docker-compose.yml</code> | <code>/opt/owncast/</code>        | Owncast: RTMP in (1935), HLS out (8080)                                                                                |
| <code>Caddyfile</code>          | <code>/etc/caddy/Caddyfile</code> | HTTPS for the Owncast watch subdomain + CORS for the storefront                                                        |
| <code>peertube/</code>          | <code>/opt/peertube/</code>       | <b>Alternative tower</b> – PeerTube with peer-to-peer (WebRTC) delivery built in; heavier, for when egress is the bill |

Two ways to cut the tower's egress as the audience grows, both P2P (viewers feed each other over WebRTC): keep Owncast and enable the `P2P_*` block in `site/index.html`, **or** swap the tower for `peertube/`, which owns the P2P and the player itself. Pick one; see `peertube/README.md` RL-Z0-PEERTUBE for the trade-offs.

The storefront is **not** served from here anymore – it lives on Cloudflare Pages (`ch0.ripostelabs.xyz`), so the VPS carries only video and Caddy's only job is to terminate TLS for the tower and hand the cross-origin page the CORS header it needs to pull the stream. See `vps/Caddyfile`.

---

Setup order and hardening (change the default admin password + stream key FIRST): see docs/pdf/docs-build-guide.pdf, Phase 1. If you run the now-playing bridge, also create an access token at /admin/access-tokens with the **set stream title** scope.
